

Online Appendix to “Global Impact of a Unilateral Waste Trade Regulation”

Prakrati Thakur*

Rensselaer Polytechnic Institute

A Waste Generation Data

I assume that $\mathcal{G}_{mit} = \lambda_{mi}\mathcal{M}_{it}$, where m is a waste material, $\mathcal{M}_{it}$ is total municipal waste generated in country i in year t , and λ_{mi} is a scalar that reflects the share of type m in waste generation. The municipal waste generation data, however, are available for only a single year, 2016 (Kaza et al., 2018). To obtain a time-series for each country, I first estimate the cross-sectional relationship between $\mathcal{M}_{i,2016}$ and a set of country characteristics, such as GDP per capita and GDP via the regression $\ln(\mathcal{M}_{i,2016}) = a_0 + a_{GDP} \ln(GDP_{i,2016}) + a_{GDPpc} \ln(GDPpc_{i,2016}) + e_i$. I then project these elasticities to the time domain to obtain estimates of municipal waste generation for country i in year t from:

$$\mathcal{M}_{it} = \left(\frac{GDP_{it}}{GDP_{i,2016}} \right)^{a_{GDP}} \left(\frac{GDPpc_{it}}{GDPpc_{i,2016}} \right)^{a_{GDPpc}} W_{i,2016}. \quad (1)$$

The λ_{mi} are calibrated based on the waste composition across countries in the literature. With the exception of yarn, gold, and platinum, Kaza et al. (2018) also provides the share of each waste type in my sample in overall municipal waste generation (See Table A.1). However, the biggest source of waste generation are the industries, not households. I assume that industrial waste generation is proportional to the size of a country’s industrial sector, which is strongly

*Department of Economics, Russell Sage Laboratory, Rensselaer Polytechnic Institute, 110 8th Street, Troy, NY 12180. Email: thakup@rpi.edu

correlated with GDP and municipal waste generation. As industries account for 94-97% of waste generation (Liboiron, 2016; Kaza et al., 2018), I scale up λ_{mi} by a factor of 20. My results are robust to an alternative scaling factor of 15.

Table A.1: Waste Composition across Income Groups

This table provides the waste composition, in percentages, from (Kaza et al., 2018) across four income groups of countries. The four income groups are as follows: High Income Countries (HIC), Upper-Middle Income Countries (UMC), Lower-Middle Income Countries (LMC), Low Income Countries (LIC).

Group	Glass	Metal	Organic	Paper	Plastic	Rubber/Leather	Wood
HIC	5	6	32	25	13	4	4
UMC	4	2	54	12	11	1	1
LMC	3	2	53	12.5	11	0.5	1
LIC	1	2	56	7	6.4	0.3	0.3

B Additional Figures and Tables

Figure A.1: China's Import Quantity of Treated and Control Commodities

This figure shows China's total import quantity of commodities in the treated and control groups between 2014-2020. The dashed line represents the year right before the announcement of Operation National Sword in 2017. For both treated and control groups, quantities in each year have been normalized by the respective 2016 quantity.

Figure A.2: Dynamic Impact on Imports by China - Alternative Control Group

This figure presents the results from estimation of Equation (8) after adding an interaction between $\sum_{s \neq 2016} Treat \times \mathbf{1}(t = s)$ and $\mathbf{1}(j = \text{China})$. The black bars represent the total impact on rest-of-the-world (ROW) while the red bars represent the total impact on China. The solid circles are point estimates, the thick lines are 90% confidence intervals, and the thin lines are 95% confidence intervals.

Figure A.3: Dynamic Impact on Imports by China and Low-Income Countries - Alternative Control Group

This figure presents the results from estimation of Equation (8) after adding an interaction between $\sum_{s \neq 2016} Treat \times \mathbb{1}(t = s)$ and $\mathbb{1}(j = \text{China})$ and an interaction between $\sum_{s \neq 2016} Treat \times \mathbb{1}(t = s)$ and $\mathbb{1}(j = \text{Low-income})$. The black bars represent the total impact on rest-of-the-world (ROW), the red bars represent the total impact on China, and the blue bars represent the total impact on lower-income countries. The solid circles are point estimates, the thick lines are 90% confidence intervals, and the thin lines are 95% confidence intervals.

Figure A.4: Dynamic Impact on Imports by Waste Value - Alternative Control Group

This figure presents the results from estimation of event-study version of Equation (9) where $n \in \{\text{High-value waste}, \text{Low-value waste}\}$ after including interactions of $\sum_{n \neq \text{Regular}} \mathbf{1}(m = n) \times \sum_{s \neq 2016} \mathbf{1}(t = s)$ with $\mathbf{1}(j = \text{China})$ and with $\mathbf{1}(j = \text{Low-income})$. The left panel shows the total impact on imports of high-value waste for different country groups while the right panel shows the total impact on imports of low-value waste for different country groups. The black bars represent the total impact on rest-of-the-world (ROW), the red bars represent the total impact on China, and the blue bars represent the total impact on lower-income countries. The solid circles are point estimates, the thick lines are 90% confidence intervals, and the thin lines are 95% confidence intervals.

Figure A.5: Placebo Test with Fake Treatment Year - Alternative Control Group

This figure shows a histogram of the absolute value of the test statistics on $Treat \times Post$ from estimation of Equation (7) after dropping observations for the years post the announcement of the ban. Each test statistic corresponds to a different year, 2015-16, serving as the fake treatment year and a different set of fixed effects and controls, as in models (1)-(4) in Table 3.

Figure A.6: Placebo Test with Fake Treated Waste Type - Alternative Control Group

This figure shows a histogram of the absolute value of the test statistics on $Treat \times Post$ from estimation of Equation (7) after dropping observations for the treated waste types. Each test statistic corresponds to a different set of control waste materials serving as the fake treated group and a different set of fixed effects and controls, as in models (1)-(4) in Table 3.

Table A.2: HS6 Categories of Waste

This table lists the HS6 codes under each waste type.

Type	HS6 Codes
Glass	700100
Gold	711291
Metal	261900, 262011, 262019, 262021, 262029, 262030, 262040, 262060, 262091, 262099, 262190, 720410, 720421, 720429, 720430, 720441, 720449, 720450, 740400, 750300, 760200, 780200, 790200, 800200, 810110, 810197, 810210, 810297, 810330, 810420, 810530, 810600, 810730, 810830, 810930, 811020, 811090, 811100, 811213, 811219, 811222, 811229, 811252, 811259, 811292, 811299
Organic	180200, 230210, 230230, 230240, 230250, 230310, 230320, 230330, 230800
Paper	470620, 470691, 470692, 470693, 470710, 470720, 470730, 470790
Plastic	391510, 391520, 391530, 391590
Platinum	711292
Rubber/Leather	400400, 401700, 411520
Wood	440131, 440139, 450190, 680800
Yarn	500300, 500400, 500500, 500600, 500720, 510310, 510320, 510330, 520210, 520291, 520299, 530130, 530290, 530390, 530500, 550510, 550520, 620610, 621410, 621510, 631010, 631090

Table A.3: Dynamic Impact on China

This table presents the results from estimation of Equation (8) after adding the interaction between $\sum_{s \neq 2016} \text{Treat} \times \mathbb{1}(t = s)$ and $\mathbb{1}(j = \text{China})$. Each column corresponds to a different set of fixed effects and controls. Standard errors clustered by exporter-importer pair in parentheses. Significance codes: *** p<0.01, ** p<0.05, * p<0.1

Table A.14: Extensive Margin - Alternative Control Group

This table presents the results from estimation of Equation (10) after adding an interaction of $Treat \times Post$ with $\mathbb{1}(j = \text{China})$. Each column corresponds to a different set of fixed effects and controls. Standard errors clustered by exporter-importer pair in parentheses. Significance codes: *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$

	Quantity			
	(1)	(2)	(3)	(4)
Treat $\times$ Post	0.026** (0.010)	0.054*** (0.019)	0.022** (0.010)	0.021* (0.011)
Treat $\times$ Post $\times \mathbb{1}(j = \text{China})$	-0.212*** (0.066)	-0.428** (0.166)	-0.170** (0.070)	-0.098 (0.076)
